(54) Title: COMPOSITIONS AND METHODS FOR ENZYMATIC DETACHMENT OF BACTERIAL AND FUNGAL BIOFILMS

(57) Abstract: Isolated nucleic acid sequences and amino acid sequences for soluble, β -N-acetylglucosaminidase or active fragments or variants thereof which promote detachment of bacterial cells from a biofilm are provided. An isolated mutant bacteria which forms biofilm colonies which tightly adhere to surface but which are unable to release cells into the medium or spread over the surface is also provided. In additions, methods are described for modulating detachment of bacterial cells from biofilm by mutating soluble, β -N-acetylglucosaminidase or altering its expression or activity are also provided. Also provided are compositions, methods and devices for preventing, inhibiting and treating bacterial infections.

WO 2004/061117 A2

Compositions and Methods for Enzymatic Detachment of
Bacterial and Fungal Biofilms

Introduction

This application claims the benefit of priority from
5 U.S. Provisional Application Serial No. 60/435,817, filed
December 20, 2002, which is herein incorporated by
reference in its entirety.

Field of the Invention

The present invention provides isolated nucleic acid
10 sequences and amino acid sequences encoded thereby for the
protein, soluble, β -N-acetylglucosaminidase or dispersin B,
and active fragments and variants thereof, which promote
detachment of bacterial cells from biofilms. Vectors
comprising the nucleic acid sequences as well as host cells
15 expressing the dispersin B protein or active fragments or
variants thereof are also provided. A biofilm detachment
mutant of *A. actinomycetemcomitans* is also described. The
nucleic acid and amino acid sequences of the present
invention are useful in methods for modulating detachment
20 of bacterial or fungal cells from biofilms as well as in
methods for identifying agents which modulate detachment of
bacterial or fungal cells from biofilms. Thus, these
nucleic acid and amino acid sequences and agents are
expected to be useful in the prevention and treatment of
25 bacterial or fungal infections and in disinfectant and
antiseptic solutions.

Background of the Invention

Biofilms are populations of bacteria or fungi growing
attached to an inert or living surface. Mounting evidence

- 2 -

has shown that biofilms constitute a significant threat to human health. The Public Health Service estimates that biofilms are responsible for more than 80% of bacterial infections in humans (National Institutes of Health, 1998 RFA# DE-98-006). Examples of diseases caused by biofilms include dental caries, periodontitis, cystic fibrosis pneumonia, native valve endocarditis, and otitis media (Costerton et al. Science 1999 284:1318-1322), as well as infection of various medical devices such as urinary catheters, mechanical heart valves, cardiac pacemakers, prosthetic joints, and contact lenses (Donlan, R. M. 2001 Emerging Infect. Dis. 7:277-281). Fungi also form biofilms of clinical significance, for example Candida infections. Biofilm infections afflict tens of millions of patients in the U.S. annually and require a significant expenditure of health care dollars (Costerton et al. Science 1999 284:1318-1322). Bacteria growing in biofilms exhibit increased resistance to antimicrobial agents and are nearly impossible to eradicate. New methods for treating biofilm infections are needed.

Bacteria in a biofilm are enmeshed in an extracellular polysaccharide (EPS) substance that holds the bacteria together in a mass, and firmly attaches the bacterial mass to the underlying surface. Previous studies have demonstrated that enzymes that degrade EPS are capable of causing the detachment of cells from biofilms. For example, over expression of alginate lyase, an enzyme that catalyzes the degradation of the EPS alginate, causes colonies of *Pseudomonas aeruginosa* to become less adherent to surfaces (Boyd, A. and Chakrabarty, A. M. Appl. Environ. Microbiol. 1994 60:2355-2359). Alginate lyase has been suggested for use in treating *P. aeruginosa* infections in the lungs of cystic fibrosis patients (Mrsny et al. Pulm. Pharmacol. 1994 7:357-366). A similar polysaccharide lyase has been shown to be produced by *P. fluorescens* (Allison et

- 3 -

al. FEMS Microbiol. Lett. 1998 167:179-184). Two other EPS-degrading enzymes, endo- β -1,4-mannanase from the plant pathogen *Xanthomonas campestris* (Dow et al. Proc. Nat. Acad. Sci. USA 2003 100:10995-11000) and disaggregatase from the methanogenic archaeobacterium *Methanosarcina mazei* (Liu et al. Appl. Environ. Microbiol. 1985 49:608-613), have also been shown to cause biofilm cell detachment. In the case of *X. campestris*, production of the EPS-degrading enzyme was required for full virulence of the bacteria in plants. Detachment of cells from biofilm colonies of the dental pathogen *Streptococcus mutans* was shown to be caused by an unidentified endogenous enzymatic activity (Lee et al. Infect. Immun. 1996 64:1035-1038). A complex mixture of polysaccharide-hydrolyzing enzymes was shown to remove biofilms from steel and polypropylene substrata (Johansen et al. Appl. Environ. Microbiol. 1997 63:3724-3728). These findings indicate that EPS-degrading enzymes can potentially be used as agents to remove biofilms from surfaces.

Although enzymes are commonly used to remove biofilms in industrial environments, no studies have investigated the potential use of enzymes as agents for the removal of biofilms in clinical environments. Of particular concern in the clinic are biofilm infections of indwelling medical devices, especially intravascular catheters. Catheter infections are common in hospitalized patients and are associated with high levels of morbidity and mortality. A promising new approach to treating these infections is the use of catheters that are coated or impregnated with antimicrobial agents such as antibiotics (Schierholz et al. J. Antimicrobial. Chemother. 2000 46:45-50), silver (Bechert et al. Infection 1999 27:S24-S29), and peptide quorum-sensing inhibitors (Balaban et al. J. Infect. Dis. 2003 187:625-630). Numerous studies have demonstrated that medical devices with antimicrobial activity decrease the

- 4 -

risk of bacterial colonization and infection (Tcholakian, R. K. and Raad, I. I. Antimicrob. Agents Chemother. 2001 45:1990-1993).

The present invention provides isolated proteins and
5 active fragments and variants thereof and nucleic acid
sequences encoding such proteins and active fragments and
variants thereof involved in detachment of bacterial cells.
Methods for modulating detachment of biofilm cells of
bacteria or fungi and identifying agents which modulate
10 bacterial or fungal detachment via these proteins and
active fragments and variants thereof and/or nucleic acid
sequences are also provided.

Summary of the Invention

An object of the present invention is to provide
15 isolated proteins and active fragments and variants thereof
which promote detachment of bacterial or fungal cells from
a biofilm. The isolated proteins are referred to herein as
soluble, β -N-acetylglucosaminidase or dispersin B.

Another object of the present invention is to provide
20 isolated nucleic acid sequences encoding soluble, β -N-
acetylglucosaminidase and active fragments and variants
thereof as well as vectors comprising these sequences and
host cells expressing the vectors.

Another object of the present invention is to provide
25 methods for modulating detachment of bacterial or fungal
cells from biofilms. In one embodiment the method
comprises mutating the bacterial cells to inhibit
detachment of bacterial cells from biofilms. In another
embodiment, the method comprises increasing expression
30 and/or levels of soluble, β -N-acetylglucosaminidase or
active fragments or variants thereof in the bacterial or
fungal cells so that detachment is increased. In yet
another embodiment, the method comprises decreasing
expression and/or levels of soluble, β -N-

- 5 -

acetylglucosaminidase or active fragments or variants thereof or inhibiting activity of soluble, β -N-acetylglucosaminidase or active fragments or variants thereof so that detachment of bacterial cells is decreased.

5 Another object of the present invention is to provide an isolated mutant of *Actinobacillus actinomycetemcomitans* which forms biofilm colonies which tightly adhere to surface but which are unable to release cells into the medium or spread over the surface.

10 Another object of the present invention is to provide a method for identifying agents which modulate detachment of bacterial or fungal cells from biofilms which comprises assessing the ability of an agent to modulate activity and/or levels and/or expression of soluble, β -N-acetylglucosaminidase.

15 Another object of the present invention is to provide compositions and methods for using these compositions to prevent the dissemination of infectious bacteria via administration of an agent which inhibits soluble, β -N-acetylglucosaminidase expression and/or activity in the bacterial cells.

20 Another object of the present invention is to provide compositions and methods for preventing or inhibiting attachment of infectious bacteria or fungi to a surface or removing infectious bacteria or fungi from a surface which comprises treating the surface with soluble, β -N-acetylglucosaminidase, or an active fragment or variant thereof.

25 Yet another object of the present invention is to provide PCR primer pairs and kits comprising such primer pairs that can be used to identify additional bacterial species with homologues of soluble, β -N-acetylglucosaminidase.

- 6 -

Brief Description of the Figure

Figure 1 provides a clustal alignment of exemplary dispersin B orthologs of the present invention from *A. actinomycetemcomitans* strain CU1000N (SEQ ID NO:2), *A. actinomycetemcomitans* strain IDH781 (SEQ ID NO:6), *Haemophilus aphrophilus* strain NJ8700 (SEQ ID NO:8), *A. ligniersii* strain 19393 (SEQ ID NO:4), and *A. pleuropneumoniae* strain IA5 (SEQ ID NO:10).

10 Detailed Description of the Invention

The small, gram-negative coccobacillus *Actinobacillus actinomycetemcomitans* is a common inhabitant of the human oral cavity (King, E.O. and Tatum, H.W. J. Infect. Dis. 1962 111:85-94). *A. actinomycetemcomitans* has been implicated as the causative agent of localized juvenile periodontitis, a severe and rapid form of periodontal disease that affects adolescents (Zambon, J.J. J. Clin. Periodontol 1985 12:1-20). *A. actinomycetemcomitans* can also enter the submucosa and cause infective endocarditis and other non-oral infections (Kaplan et al. Rev. Infect. Dis. 1989 11:46-63).

When cultured in broth, fresh clinical isolates of *A. actinomycetemcomitans* form tenacious biofilms on surfaces such as glass, plastic and saliva-coated hydroxyapatite (Fine et al. Arch. Oral. Biol. 1999 44:1063-1076; Fine et al. Microbiol. 1999 145:1335-1347; Fine et al. Arch. Oral Biol. 2001 46:1065-1078; Haase et al. Infect. Immun. 1999 67:2901-2908; Inouye et al. FEMS Microbiol. Lett. 1990 69:13-18; Kachlany et al. J. Bacteriol. 2000 182:6169-6176; Kachlany et al. Mol. Microbiol. 2001 40:542-554; Kagermeier, A. S., and London, J. Infect. Immun. 1985 47:654-658; Kaplan, J. B., and Fine, D.H. Appl. Environ. Microbiol. 2002 68:4943-4950; King, E. O. and Tatum, H.W. J. Infect. Dis. 1962 111:85-94; Rosan et al. Oral.

- 7 -

Microbiol. Immunol. 1988 3:58-63). Nearly all of the cells grow attached to the surface while the broth remains clear and is often sterile (Fine et al. Arch. Oral. Biol. 1999 44:1063-1076). The dense biofilm that forms on the
5 surface is resistant to removal by agents such as detergents, proteases, heat, sonication and vortex agitation (Fine et al. Arch. Oral. Biol. 1999 44:1063-1076), and can be removed only by mechanical scraping. A. actinomycetemcomitans biofilm colonies exhibit increased
10 resistance to antimicrobial agents when compared to cells grown in planktonic form (Fine et al. J. Clin. Periodontol. 2001 28:697-700).

Tight adherence has been shown to play an important role in the ability of A. actinomycetemcomitans to colonize
15 the mouths of rats (Fine et al. Arch. Oral Biol. 2001 46:1065-1078.), and is believed to have an equally important role in its ability to colonize humans. The tight adherence to surfaces is dependent on the presence of long, bundled pili (fimbriae) that form on the surface of the
20 cell (Inouye et al. FEMS Microbiol. Lett. 1990 69:13-18; Rosan et al. Oral. Microbiol. Immunol. 1988 3:58-63). Mutations in *flp-1*, which encodes the major pilin protein subunit, result in cells that fail to produce fimbriae or adhere to surfaces (Kachlany et al. Mol. Microbiol. 2001
25 40:542-554).

Biofilm colonies of A. actinomycetemcomitans have been shown to release cells into liquid medium which then attach to the surface of the culture vessel and form new colonies, enabling the biofilm to spread (Kaplan, J. B. and
30 Fine D. H. Appl. Environ. Microbiol. 2002 68: 4943-4950.).

One aspect of the present invention relates to a mutant of A. actinomycetemcomitans that forms biofilm colonies which are tightly adherent to surfaces but which are unable to release cells into the medium or spread over
35 the surface. The biofilm detachment mutant of A.

- 8 -

actinomycetemcomitans is referred to herein as mutant JK1023. To produce the *A. actinomycetemcomitans* biofilm detachment mutant JK1023, the *A. actinomycetemcomitans* strain CU1000N was mutagenized with transposon IS903 ϕ kan.

5 The mutant strain (designated JK1023) was then isolated. This mutant strain displays a colony morphology on agar that is rougher than the wild-type *A. actinomycetemcomitans* rough-colony phenotype (Fine et al. Microbiol. 1999 145:1335-1347; Haase et al. Infect. Immun. 1999 67:2901-10 2908; Inouye et al. FEMS Microbiol. Lett. 1990 69:13-18). JK1023 colonies had a hard texture and were extremely difficult to remove from the agar surface. When cultured in broth, strain JK1023 produced biofilm colonies which were similar in size and shape to those of the wild-type strain, 15 but which failed to produce satellite colonies on the surface of the culture vessel. Adherence of JK1023 cells to polystyrene was equal to that of wild-type strain CU1000N as measured by a 96-well microtiter plate binding assay.

To demonstrate that biofilm colonies of mutant strain JK1023 of the present invention were deficient in biofilm 20 cell detachment, biofilm colonies were grown for 24 hours on polystyrene rods suspended in broth in the wells of a 24-well microtiter plate. The amount of biofilm cell detachment was then quantified by staining the bacteria 25 growing on the bottom of the well with crystal violet. Colonization at the bottom of the well results from cells that detach from the biofilm colonies growing on the polystyrene rod and fall to the bottom of the well. In this assay, biofilm colonies of strain JK1023 produced 30 significantly less growth on the bottom of the well than the wild-type strain ($P < 0.01$, unpaired two-tailed t test). These data indicate that mutant strain JK1023 exhibited a wild-type surface attachment phenotype but a decreased biofilm cell detachment phenotype when compared 35 to the wild-type strain CU1000N.

- 9 -

DNA sequence analysis of the region surrounding the transposon insertion site of this mutant strain revealed the insertion to be in a 1,143 bp open reading frame designated herein as *dspB*. The *dspB* gene from strain
5 CU1000 was predicted to encode a protein, referred to herein as dispersin B, having 381 amino acid residues with a molecular mass of 43.3 kDa. The 5' end of *dspB* contained a predicted signal peptide, suggesting that dispersin B may be a secreted protein.

10 In addition to *A. actinomycetemcomitans*, *dspB* nucleic acid sequences or fragments have also been isolated from *Actinobacillus pleuropneumoniae*, *Haemophilus aphrophilus* and *Actinobacillus ligniersii*. *DspB* is not present in the genomes of *Haemophilus influenzae*, *Pasteurella multocida*,
15 *Mannheimia haemolytica*, *Actinobacillus equuli* and *Haemophilus ducreyi* among the strains that were tested.

Accordingly, another aspect of the present invention relates to nucleic acid sequences encoding dispersin B or active fragments and variants thereof as well as amino acid
20 sequences of dispersin B and active fragments and variants thereof. Also encompassed by the present invention are vectors comprising these nucleic acid sequences as well as host cells comprising the vectors which express dispersin B or an active fragment thereof.

25 By the term "nucleic acid sequence" as used herein it is meant to include, but is not limited to, unmodified RNA or DNA or modified RNA or DNA. Thus, by nucleic acid sequence it is meant to be inclusive of single- and double-stranded DNA, DNA that is a mixture of single- and double-
30 stranded regions, single- and double-stranded RNA, and RNA that is mixture of single- and double-stranded regions, hybrid molecules containing DNA and RNA that may be single-stranded or, more typically, double-stranded or a mixture of single- and double-stranded regions. Further, the DNA
35 or RNA sequences of the present invention may comprise a

- 10 -

modified backbone and/or modified bases. A variety of modifications to DNA and RNA are known in the art for multiple useful purposes. The term "nucleic acid sequence" as it is employed herein embraces such chemically,

5 enzymatically or metabolically modified forms of nucleic acid sequences, as well as the chemical forms of DNA and RNA characteristic of viruses and cells, including simple and complex cells.

The DNA sequence of *dspB* from strain CU1000 was
10 deposited into GenBank under accession no. AY228551 and released on August 4, 2003. The nucleic acid sequence for this DNA is SEQ ID NO:1. Nucleic acid sequences encoding orthologs of dispersin B protein have been identified in *A. ligniersii* strain 19393, *A. actinomycetemcomitans* strain
15 IDH781, *Haemophilus aphrophilus* strain NJ8700 and *A. pleuropneumoniae* strain IA5 and are depicted in SEQ ID NO:3, 5, 7 and 9, respectively. Accordingly, preferred isolated nucleic acid sequences of the present invention comprise SEQ ID NO:1, 3, 5, 7 or 9.

20 Also included within the present invention are allelic variants of the exemplified *dspB* nucleic acid sequences of SEQ ID NO:1, 3, 5 7 or 9 encoding proteins with similar enzymatic activities to dispersin B and nucleic acid sequences with substantial percent sequence
25 identity to the exemplified *dspB* nucleic acid sequences of SEQ ID NO: 1, 3, 5, 7 or 9 encoding proteins with similar enzymatic activities.

By the term "allelic variant" as used herein it is meant one of two or more alternative naturally occurring
30 forms of a gene, each of which comprises a unique nucleic acid sequence. Allelic variants encompassed by the present invention encode proteins with similar or identical enzymatic activities.

The term "percent sequence identity" as used herein
35 with respect to nucleic acid sequences refers to the

- 11 -

residues in two nucleic acid sequences which are the same when aligned for maximum correspondence. The length of sequence identity comparison is preferably over a length of at least about 9 contiguous nucleotides, more preferably
5 about 18 contiguous nucleotides, and even more preferably at least about 30 to 50 contiguous nucleotides or more. Various algorithms well known in the art are available for measuring nucleic acid sequence identity. Examples include, but are not limited to, FASTA (including FASTA2
10 and FASTA3), Gap and Bestfit, which are programs in Wisconsin Package Version 10.0, Genetics Computer Group (GCG), Madison, Wisconsin.

By "substantial percent sequence identity" when referring to a nucleic acid sequence or fragment thereof,
15 of the present invention, it is meant that when optimally aligned with appropriate nucleotide insertions or deletions with another nucleic acid (or its complementary strand), at least about 50% of the nucleotide bases as measured by any well known algorithm of sequence identity, such as FASTA,
20 BLAST or Gap are the same. For purposes of the present invention, more preferably, at least about 60% to 70%, even more preferably 80% to 90%, and most preferably at least about 95-98% of the nucleotide bases, as measured by any well known algorithm of sequence identity, such as FASTA,
25 BLAST or Gap, are identical.

Nucleic acid sequences sharing substantial percent sequence identity and encoding proteins with similar functional activity are referred to herein as orthologues.

Deduced amino acid sequences of dispersin B and
30 exemplary orthologues thereof are shown in Figure 1. Specifically, the amino acid sequence of dispersin B of *A. actinomycetemcomitans* strain CU1000N (SEQ ID NO:2), and orthologs of dispersin B from *A. actinomycetemcomitans* strain IDH781 (SEQ ID NO:6), *Haemophilus aphrophilus* strain
35 NJ8700 (SEQ ID NO:8), *A. ligniersii* strain 19393 (SEQ ID

- 12 -

NO:4), and *A. pleuropneumoniae* strain IA5 (SEQ ID NO:10) are shown.

There are similarities between the amino acid sequence of dispersin B and these orthologs and the
5 consensus sequence of the family 20 glycosyl hydrolase. More specifically, amino acid residues 40 to 297 of the predicted dispersin B protein sequence are homologous to the catalytic domain of the family 20 glycosyl hydrolases (NCBI Conserved Domain Database accession Number
10 pfam00728). This family of enzymes includes bacterial chitinases, chitobiases and lacto-N-biosidases (Sano et al. J. Biol. Chem. 1993 268:18560-18566; Tews et al. Gene 1996 170:63-67; Tsujibo et al. Biochim. Biophys. Acta 1998 1425:437-440.), and eukaryotic hexosaminidases (Graham et
15 al. J. Biol. Chem. 1988 263:16823-16829). A protein related to *A. actinomycetemcomitans* dispersin B is lacto-N-biosidase of *Lactococcus lactis* (GenBank accession no. AAK05592), which displays 28% identity over 281 amino acid residues not counting gaps and terminal extensions.
20 Similarity between dispersin B and lacto-N-biosidases is high in the regions surrounding Arg47 and the acidic amino acid pair Asp202 and Glu203. These residues have been shown to participate in substrate binding and catalysis in other family 20 glycosyl hydrolases (Mark et al. J. Biol.
25 Chem. 2001 276:10330-10337; Mark et al. J. Biol. Chem. 1998 273:19618-19624; Prag et al. J. Mol. Biol. 2000 300:611-617). The C-terminal half of dispersin B contained three Trp residues that were conserved in *L. lactis* lacto-N-biosidase (positions 236, 279, and 353). Multiple Trp
30 residues are present in the C-terminal regions of the catalytic domains of all family 20 glycosyl hydrolases (Graham et al. J. Biol. Chem. 1988 263:16823-16829; Tews et al. Gene 1996 170:63-67). These Trp residues line the part of the substrate binding pocket that is complementary to
35 the hydrophobic surfaces of the hexosamine sugar ring (Tews

- 13 -

et al. Nature Struct. Biol. 1996 3:638-648). It is expected that mutation of amino acids in these regions of dispersin B and its orthologs will alter enzymatic activity.

In a preferred embodiment an isolated amino acid
5 sequence of the present invention comprises SEQ ID NO:2, 4, 6, 8 or 10 or an active fragment or variants thereof. Preferred active fragments are those comprising a portion of the amino acid sequence of SEQ ID NO:2, 4, 6, 8 or 10 with similarities to the consensus sequence of the family
10 20 glycosyl hydrolase.

"Active variants" or "functionally equivalent variants" as used herein are polypeptide sequences structurally different from the dispersin B protein, but having no significant functional difference from the
15 protein. For example, when orthologous polypeptide sequences from various strains of *A. actinomycetemcomitans* are aligned, divergence in amino acid sequence is observed, usually 0 to 10 percent (Kaplan et al. Oral Microbiol. Immunol. December 2002 17:354-359; Kaplan et al. Infect.
20 Immun. 2001 69:5375-5384). Proteins displaying this amount of divergence are considered functionally equivalent variants because of the fact that mixing of genetic alleles that encode these variants is often observed in populations (Kaplan et al. Oral Microbiol. Immunol. December 2002
25 17:354-359). The dispersin B sequence from *A. actinomycetemcomitans* strain IDH781 (SEQ ID NO:6), therefore, is expected to be a functionally equivalent or active variant of SEQ ID NO:2, and is included in the scope of the present invention. Similarly, dispersin B sequences
30 from other strains of *A. actinomycetemcomitans*, such as those that exhibit different serotypes, restriction fragment length polymorphism genotypes, 16S ribosomal RNA genotypes, or arbitrarily-primed PCR genotypes that are commonly observed among phylogenetically diverse strains
35 isolated from different subjects (Kaplan et al. J. Clin.

- 14 -

Microbiol. 2002 40:1181-1187; Kaplan et al., Oral
Microbiol. Immunol. December 2002 17:354-359), are also
expected to be functionally equivalent or active variants
of SEQ ID NO:2, and are included in the scope of the
5 present invention.

Similarly, orthologous proteins from phylogenetically
diverse species of bacteria are usually functionally
equivalent or active variants, as evidenced by the fact
that a common method for cloning genes of interest into
10 plasmids is to screen a plasmid library for plasmids that
complement a genetic mutation in a different species of
bacteria (Kaplan et al. J. Mol. Biol. 1985 183:327-340).
This is especially true of bacterial enzymes. Orthologous
enzymes of different bacterial species can exhibit up to
15 50% divergence or greater, yet still utilize the identical
substrate, catalyze the same chemical reaction, and produce
the same product. This sequence divergence results from
genetic drift coupled with fixation of selected genetic
changes in the population. The genetic changes that are
20 selected and fixed are those that alter characteristics of
the enzyme other than substrate, reaction, and product, as
for example, reaction rate, pH optimum, temperature
optimum, level of expression, and interactions with other
enzymes, such that these genetic changes confer upon a
25 bacterial cell a selective advantage in its environment.
Since *A. actinomycetemcomitans* is genetically closely
related to *A. pleuropneumoniae* (Dewhirst et al. J.
Bacteriol. 1992 174:2002-2013) and produces a biofilm
similar to that produced by *A. actinomycetemcomitans*, which
30 as demonstrated herein detaches upon contact with *A.*
actinomycetemcomitans dispersin B, it is expected that the
A. pleuropneumoniae DspB homologue identified in SEQ ID
NO:10 is a functionally equivalent or active variant of SEQ
ID NO:2, and is included in the scope of the present
35 invention. Similarly, since *Actinobacillus ligniersii* is

- 15 -

genetically closely related to *Actinobacillus pleuropneumoniae* (Dewhirst et al. J. Bacteriol. 1992 174:2002-2013) and *Haemophilus aphrophilus* is genetically closely related to *A. actinomycetemcomitans* (Dewhirst et al. J. Bacteriol. 1992 174:2002-2013; Kaplan et al. J. Clin. Microbiol. 2002 40:1181-1187), and since both *A. ligniersii* and *Haemophilus aphrophilus* produce biofilms similar to that produced by *A. actinomycetemcomitans*, it is expected that the *Actinobacillus ligniersii* and *Haemophilus aphrophilus* dispersin homologues identified in SEQ ID NO:4 and SEQ ID NO:8, respectively, are functionally equivalent or active variants of SEQ ID NO:2, and are included in the scope of the present invention.

The above mentioned examples demonstrate functionally equivalent or active variants of *A. actinomycetemcomitans* dispersin B that occur in nature. As will be understood by those of skill in the art upon reading this disclosure, however, artificially produced genes that encode functionally equivalent or active variants of *A. actinomycetemcomitans* dispersin B can also be produced routinely in accordance with the teachings herein using various well known genetic engineering techniques. For example, a genetically engineered dispersin B enzyme that lacks 20 N-terminal amino acid residues, and also contained a 32 amino acid residue C-terminal tail, which if functionally equivalent to the natural dispersin B enzyme has been produced. It has also been shown that the methionine residue at the N-terminus of this genetically engineered dispersin B enzyme, when expressed in *E. coli*, was removed by the action of methionine aminopeptidase, yet the absence of the methionine did not affect enzyme activity. It has also been shown that cleavage of the C-terminal 28 amino acid residues from this genetically engineered dispersin B enzyme has no affect on enzyme

- 16 -

activity. These examples demonstrate that artificial genes can be produced that encode functionally equivalent variants of *A. actinomycetemcomitans* dispersin B. These artificially produced functionally equivalent variants of
5 *A. actinomycetemcomitans* dispersin B are included in the scope of the present invention.

The above mentioned examples demonstrate genetically-engineered, functionally equivalent variants of *A. actinomycetemcomitans* dispersin B that contain either a
10 deletion of amino acid residues at the N-terminus of the protein, or the fusion of an additional polypeptide at the C-terminus of the protein. It is expected that other genetically-engineered alterations, such as the fusion of an additional polypeptide at the N-terminus of the protein,
15 a deletion of amino acid residues at the C-terminus of the protein, internal deletions and insertions of amino acid residues, and amino acid substitutions, would also result in functionally equivalent variants of *A.*

actinomycetemcomitans dispersin B. Information about which
20 deletions, insertions, and amino acid substitutions would produce functionally equivalent variants of *A.*

actinomycetemcomitans dispersin B can be obtained from amino acid sequence alignments, and from commonly available computer software that predicts polypeptide secondary
25 structures based on both primary amino acid sequences and on amino acid sequence alignments with homologous proteins having known three-dimensional structures. *A.*

actinomycetemcomitans dispersin B, for example, is a member of the family 20 glycosyl hydrolases, a family that
30 includes several well-studied enzymes, and a family represented by numerous homologous primary amino acid sequences in the public databases. In some cases, three-dimensional structures of family 20 glycosyl hydrolases are known (Tews et al. Nature Struct. Biol. 1996 3:638-648).

- 17 -

All family 20 glycosyl hydrolases exhibit a $(\beta\alpha)_8$ -barrel motif (also known as a TIM-barrel motif; Tews et al. Nature Struct. Biol. 1996 3:638-648; Prag et al. J. Mol. Biol. 2000 300:611-617), which is by far the most common enzyme fold in the Protein Data Bank (PDB) database of known protein structures. It is estimated that 10% of all known enzymes have this domain (Wierenge, R. K., FEBS Lett. 2001 492:193-198). The $(\beta\alpha)_8$ -barrel motif is seen in many different enzyme families, catalyzing completely unrelated reactions. The availability of numerous homologous primary amino acid sequences, combined with the availability of the three-dimensional structures of several *A. actinomycetemcomitans* dispersin B homologues, forms the basis of these sequence alignments and secondary structure predictions. For example, the $(\beta\alpha)_8$ -barrel motif consists of eight α -helices and eight β -strands such that eight parallel β -strands form a barrel on the inside of the protein, which are covered by eight α -helices on the outside of the protein. Based on the above mentioned protein sequence alignments and structural predictions, it is expected that the eight β -strands in *A. actinomycetemcomitans* DspB comprise the amino acid residues surrounding positions 41-44, 69-81, 130-134, 169-171, 189-200, 253-256, 288-300, and 348-350 of SEQ ID NO:2. Any alteration in the amino acid sequence that disrupts the β -strand architecture of these eight regions would be expected to result in a decrease in enzyme activity because of a concomitant disruption in the three-dimensional structure of the $(\beta\alpha)_8$ -barrel of the enzyme. Similarly, based on the above mentioned protein sequence alignments and structural predictions, it is expected that the eight α -helices in *A. actinomycetemcomitans* DspB comprise the amino acid residues surrounding positions 52-63, 89-93, 143-149, 176-183, 214-228, 269-284, 309-321, and 361-374 of SEQ ID NO:2. Any alteration in the amino acid sequence

- 18 -

that disrupts the α -helical architecture of these eight regions would be expected to result in a decrease in enzyme activity because of a concomitant disruption in the three-dimensional structure of $(\beta\alpha)_8$ -barrel of the enzyme.

5 Similarly, because the β -strands consist of four inward pointing side chains (pointing into the β -barrel) and four outward pointing side chains (pointing towards the α -helices), it is expected that alterations in the inward-pointing amino acid residues will reduce enzyme activity
10 because of concomitant alterations to the substrate binding pocket inside the $(\beta\alpha)_8$ -barrel, and that alterations in the outward-pointing amino acid residues will reduce enzyme activity when they interfere with the interactions between the β -strands and the α -helices. Similarly, the active site
15 of family 20 glycosyl hydrolases is always located at the C-terminal end of the eight parallel β -strands of the barrel. It is expected that alterations in the homologous region of *A. actinomycetemcomitans* dispersin B will affect enzyme activity. Similarly, it is predicted that the
20 introduction of insertions and deletions into the regions between the α -helices and the β -strands, namely in positions 45-51, 64-68, 82-88, 94-129, 135-142, 150-168, 172-175, 182-188, 201-213, 229-252, 257-268, 285-287, 301-308, 322-347, and 351-360, in SEQ ID NO:2, will not effect
25 enzyme activity. Similarly, it is expected that almost any alteration of residues 47 (Arginine), 203 (Aspartate) and 204 (Glutamate) will result in complete loss of enzyme activity, because these three residues have been shown to participate directly in substrate binding and catalysis in
30 all family 20 glycosyl hydrolases (Mark et al. J. Biol. Chem. 1998 273: 19618-19624; Prag et al. J. Mol. Biol. 2000 300:611-617; Mark et al. J. Biol. Chem. 2001 276:10330-10337). Similarly, it is expected that alteration of the three tryptophan residues at positions 236, 257 and 350, to
35 any non-aromatic amino acid residue will result in a

- 19 -

decrease in enzyme activity because these three tryptophan residues have been shown to line part of the substrate-binding pocket that is complementary to the hydrophobic surfaces of the substrate hexosamine sugar ring (Tews et al. Nature Struct. Biol. 1996 3:638-648). As a result of the locations of these essential amino acid residues in *A. actinomycetemcomitans* dispersin B, it is predicted that no more than 46 amino acid residues can be deleted from the N-terminus, and no more than 31 amino acids can be deleted from the C-terminus, without loss of enzyme activity. All of these genetic alterations that result in functionally equivalent variants are included in the scope of the present invention.

Genes encoding functionally different variants of *A. actinomycetemcomitans* dispersin B can also be produced in accordance with the teachings of the instant application using well known genetic engineering techniques. For example, as mentioned above, it is expected that almost any alteration of residues 47 (Arginine), 203 (Aspartate) and 204 (Glutamate) in SEQ ID NO:2 will result in complete loss of enzyme activity. Alternatively, variants of *A. actinomycetemcomitans* dispersin B that exhibit characteristics that may be useful in a clinical setting could also be artificially produced. For example, the temperature optimum of *A. actinomycetemcomitans* dispersin B is 30°C. It may be desirable to produce a genetically-engineered variant of dispersin B that exhibits a temperature optimum of 37°C, thereby resulting in an increased effectiveness of the enzyme or decreased cost of treatment. Such variants can be artificially produced by first creating random mutations in the *A. actinomycetemcomitans* *dspB* gene sequence, for example by using UV light or a chemical mutagen like nitrosoguanidine, and then screening large numbers of these random variants,

- 20 -

for example in a quantitative 96-well microtiter plate assay (Kaplan et al. J. Bacteriol. 2003 185:4693-4698), for ones that exhibit higher temperature optima. An alternative method is to utilize directed evolution of sequences by DNA shuffling (Christians et al. Nature Biotechnol. 1999 17:259-264; Dichek et al. J. Lipid Res. 1993 34:1393-1340), combined with a high-throughput robotic screen based upon a quantitative 96-well microtiter plate assay (Kaplan et al. J. Bacteriol. 2003 185:4693-4698) to identify variants with increased temperature optima. The aforementioned methods can also be used to produce variants of *A. actinomycetemcomitans* dispersin B that exhibit increased substantivity to biomaterials, increased pH optima, increased stability in aqueous solutions, increased reaction rate, increased stability upon desiccation, and other characteristics that could result in increased effectiveness of the enzyme or decreased cost of treatment. An alternative method that can be used to produce useful variants is site-directed mutagenesis. For example, it is expected that the eight α -helices of the $(\beta\alpha)_8$ -barrel in *A. actinomycetemcomitans* dispersin B contain many amino acid residues that are exposed on the outer surface of the enzyme, and that altering the outward-pointing amino acid residues of the eight α -helices will alter the outer surface properties of the enzyme, thereby potentially increasing the substantivity of the enzyme for biomaterials without affecting enzyme activity. Accordingly, these outward pointing amino acid residues can be systematically mutated, for example from polar residues to charged residues, and the resulting mutants screened to identify variants with increased substantivity to biomaterials. Functionally different variants of *A. actinomycetemcomitans* dispersin B that are intended to improve the clinical efficiency or cost effectiveness of the enzyme, when applied to detaching bacterial or fungal cells from

- 21 -

biofilms, are included in the scope of the present invention.

Also provided in the present invention are fusion proteins and nucleic acid sequences encoding fusion proteins. Fusion proteins of the present invention comprise an amino acid sequence for an isolated soluble, β -N-acetylglucosaminidase protein which promotes detachment of bacterial cells from a biofilm and a second polypeptide. Exemplary second polypeptides of these fusion proteins include, but are not limited to, those which facilitate purification such as a His tag, those which facilitate attachment to a surface such as an antibody or a protein such as albumin, fibronectin or thrombin, and/or those which target the enzyme to the surface of bacterial or fungal cell such as a specific bacterial or fungal receptor. Nucleic acid sequences encoding such fusion proteins comprise an isolated nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof which promotes detachment of bacterial or fungal cells from a biofilm and a second nucleic acid sequence encoding a second polypeptide. In a preferred embodiment, the second nucleic acid sequence encodes a polypeptide such as a His tag which facilitates purification, an antibody or protein such as albumin, fibronectin or thrombin which facilitates attachment of the fusion protein to a surface, or a bacterial or fungal receptor which specifically targets the fusion protein to the surface of a bacterial or fungal cell, respectively.

The dispersin B protein engineered to contain an octahistidine metal binding site at its C-terminus was expressed in *E. coli*. The protein was purified by Ni-affinity chromatography and the dispersin B portion was cleaved from the hybrid protein using thrombin. Analysis of the purified cleaved dispersin B protein by SDS-PAGE revealed the protein to migrate with an apparent molecular

- 22 -

mass of 41 kDa. The N-terminal sequence of dispersin B was XCVKGN SIYPQK (SEQ ID NO:11) (where X is an unidentified residue). This matched codons 22 to 33 of CU1000 *dspB*, thus indicating that the dipeptide Met-Asn was cleaved from the N-terminus of the dispersin B fusion protein when expressed in *E. coli*. Analysis of purified, cleaved dispersin B protein by mass spectrophotometry resulted in a single major peak with an apparent molecular mass of 41.5 kDa, consistent with the predicted molecular mass of 41.4 kDa for the cleaved and processed dispersin B protein. The yield of dispersin B expressed in *E. coli* was 30 mg of protein per liter of culture.

The ability of dispersin B to cleave the glycosidic linkages of various 4-nitrophenyl-labeled synthetic hexosamine substrates was tested in an *in vitro* enzyme assay. Dispersin B showed specificity for the 1→4 glycosidic bond of β -substituted *N*-acetylglucosaminide, consistent with the known functions of other family 20 glycosyl hydrolases (Tews et al. Nature Struct. Biol. 1996 3:638-648). Dispersin B showed no activity against α -substituted *N*-acetylglucosaminide, or against α - or β -substituted *N*-acetylgalactosamine.

The glycosyl hydrolase activity of dispersin B was optimal at pH 5.0, which is similar to the pH optima of other family 20 glycosyl hydrolases. Dispersin B displayed maximum activity at 30°C. Dispersin B glycosyl hydrolase activity was inhibited by quinacrine (Kovacs, P. and Csaba, G. Cell Biochem. Funct. 2001 19:287-290) and NAG-thiazoline (Mark et al. J. Biol. Chem. 2001 276:10330-10337), two small molecule inhibitors of family 20 β -*N*-acetylglucosaminidases.

The effects of dispersin B protein on biofilm cell detachment of *A. actinomycetemcomitans* mutant strain JK1023 were then examined. In these experiments, dispersin B

- 23 -

protein was added to growth medium of mutant strain JK1023 to determine if addition of this protein restored release of cells into the medium and dispersion. Polystyrene rods containing biofilm colonies of strain JK1023 were suspended
5 in broth containing various amount of dispersin B, and the amount of biofilm cell detachment was measured by staining the bacteria growing on the bottom of the well with crystal violet. Purified dispersin B restored the ability of mutant strain JK1023 to release cells into the medium and
10 colonize the bottom of the microtiter plate well in a dose-dependent manner. Heat-inactivated dispersin B had no effect on biofilm cell detachment of strain JK1023.

The effects of dispersin B protein on detachment of preformed biofilm colonies of *A. actinomycetemcomitans* and
15 other bacteria were also examined. In these experiments, addition of dispersin B caused the detachment of preformed biofilm colonies of wild-type strain CU1000. Dispersin B (50 µg/ml) caused a 90% reduction in the amount of surface-associated bacteria after 6 hours. Further, analysis by
20 light micrography showed that the surface of treated colonies became grainy and flocculent when compared to the smooth-textured biofilm colonies observed with mock-treated cells. Also, the surface of the culture vessel became covered with a similar grainy material which had a fibrous
25 appearance under higher power. These findings are consistent with the observed reduction in adherence of preformed biofilm colonies treated with dispersin B.

Dispersin B caused a similar reduction in biofilm density when tested against biofilm colonies of four
30 phylogenetically diverse strains of *A. actinomycetemcomitans* representing four different serotypes, a strain of the closely related bacterium *Haemophilus aphrophilus*, and two strains of the swine pathogen *Actinobacillus pleuropneumoniae*. Dispersin B did
35 not cause the detachment of biofilm colonies of *Neisseria*

- 24 -

subflava, *Cardiobacterium hominis* or *Streptococcus mitis*, bacteria which do not have biofilms comprising N-acetyl glucosamine residues.

Dispersin B also causes the detachment of

5 *Staphylococcus epidermidis* from surfaces. The Gram-positive bacterium *S. epidermidis* is the most common cause of infection associated with catheters and other indwelling medical devices. *S. epidermidis* produces an extracellular slime composed of a polysaccharide containing primarily N-

10 acetylglucosamine residues (Mack et al. J. Bacteriol. 1996 178:175; Baldassarri et al. Infect. Immun. 1996 64:3410) which enables it to form adherent films on plastic surfaces. Biofilm bacteria such as *S. epidermidis* are highly resistant to antibiotics and host defenses and

15 nearly impossible to eradicate (Costerton et al. Annu. Rev. Microbiol. 1995 49:711). Thus, attachment of this bacteria to indwelling devices such as catheters can lead to osteomyelitis, acute sepsis and death, particularly in immunocompromised patients, and is a leading cause of

20 nosocomial bloodstream and cardiovascular infections as well as morbidity in hospitalized patients (Vuong, C. and Otto, M. Microbes, Infect. 2002 4:481).

Four different strains of *S. epidermidis* isolated from infected intravenous catheters were used in these

25 experiments. All four strains contained the *ica* genetic locus and produced dark red colonies on Congo red agar, both of which are indicative of slime production (Aricola et al. J. Clin. Microbiol. 2001 39:2151; Aricola et al. Biomaterials 2002 Biomaterials 23:4233). The

30 ability of the four strains to form biofilms was measured by making serial dilutions of overnight cultures in fresh broth and then transferring the dilutions to the wells of a 96-well polystyrene microliter plate. After 16 hours of incubation, the wells were washed under running

- 25 -

tap water to remove loosely adherent cells and the bacteria remaining attached to the bottoms of the well were stained with crystal violet. As expected all four strains produced adherent biofilms as indicated by the presence of dark-
5 staining material on the bottoms of the wells. The amount of dark-staining material was quantitated by measuring its optical density at 590 nm in a microliter plate reader. When dispersin B protein was added to the wells 30 minutes prior to washing (final concentration, 40 $\mu\text{g/ml}$) little or
10 no biofilm material was evident. In contrast, heat inactivated dispersin B protein had no effect on *S. epidermidis* biofilms. Two other N-acetylglucosaminidase enzymes that are homologous to *A. actinomycetemcomitans* dispersin B, *Serratia marcescens* chitinase and jack bean β -
15 hexosaminidase, also had no effect on *S. epidermidis* biofilms. Unlike the orthologs described herein, these homologous proteins share less than 25% identity with dispersin B and do not exhibit biofilm-releasing activity. Thus, these experiments are demonstrative of dispersin B
20 enzymatic activity being responsible for removing *S. epidermidis* biofilm cells from the surfaces of the wells. Dispersin B had no effect on viability of *S. epidermidis* cells.

The amount of dispersin B protein and the length of
25 time needed to remove *S. epidermidis* biofilms from the microliter plate wells were also examined. In these experiments, multiple wells were inoculated with a 10^{-4} dilution of a *S. epidermidis* culture and the plate was incubated for 16 hours. After washing away loosely adherent
30 cells, the wells were filled with phosphate buffered saline (PBS) and then various amounts of dispersin B protein (200 pg to 120 μg per ml final concentrations) were added to the wells for various lengths of time (0 to 9 minutes). Dispersin B treatment at a concentration of 4.8 $\mu\text{g/ml}$

- 26 -

resulted in a decrease in absorbance to background levels (ca. 0.09 O.D. units) after 2 minutes. At a concentration of 40 ng/ml, dispersin B resulted in a greater than 50 percent reduction in optical density after 9 minutes (from 3.63 to 1.74 O.D. units. These data demonstrate that dispersin B causes detachment of *S. epidermidis* biofilms of clinically achievable concentrations of the enzyme.

Biofilm cell detachment was quantitated by growing *S. epidermidis* biofilms on polystyrene rods and then transferring the rods to tubes containing PBS (as a control) or PBS with 60 µg/ml of dispersin B. The tubes were incubated for 15 minutes, rinsed in PBS, and the bacteria remaining attached to the rods after treatment were removed by sonication and then quantitated by plating serial dilutions of the sonicates on agar. Mock-treated and dispersin B-treated rods were compared after staining with crystal violet. The mock-treated control rod contained a layer of dark-staining material corresponding to the thick biofilm that formed on its surface. The dispersin B-treated rod showed no trace of dark-staining material and was similar in appearance to a rod which was sonicated prior to staining and to an uninoculated rod. Quantitation of cells remaining attached to the rods revealed that dispersin B treatment resulted in a 5.8 log reduction in the number of surface-associated bacteria.

The ability of dispersin B to remove *S. epidermidis* biofilms grown attached to polyurethane and Teflon intravenous catheters was also examined. In these experiments, catheters were placed in tubes containing a 10⁻³ dilution of a *S. epidermidis* culture and incubated for 16 hours. The catheters were then rinsed with PBS and transferred to tubes containing PBS (as a control) or PBS with 60 µg/ml of dispersin B. After 5 minutes the catheters were rinsed with PBS and the biofilm bacteria

- 27 -

remaining attached to the surface were stained with methylene blue (for polyurethane catheters) or crystal violet (for Teflon catheters). The control catheters contained a layer of dark-staining material on their
5 surfaces indicating the presence of a biofilm, whereas the dispersin B-treated catheters contained no dark-staining material and were similar in appearance to uninoculated catheters.

Thus, dispersin B of the present invention is capable
10 of removing *S. epidermidis* biofilms from various plastic biomaterials.

The ability of precoating surfaces with dispersin B to prevent *S. epidermidis* biofilm formation was also demonstrated. In these experiments, polyurethane and
15 Teflon catheters in tubes containing PBS or PBS with 40 $\mu\text{g/ml}$ of dispersin B were incubated at 4°C for 24 hours. The catheters were then rinsed with PBS and transferred to tubes containing a 10^{-1} dilution of a *S. epidermidis* culture. After 6 hours, the catheters were rinsed with PBS to remove
20 loosely adherent cells and then stained as described *supra*. The surfaces of control catheters were covered with a layer of dark-staining material indicating the presence of a biofilm, whereas the surfaces of dispersin B-coated catheters contained no dark-staining material and were
25 similar in appearance to uninoculated catheters. As shown, precoating plastic catheters with dispersin B of the present invention significantly reduced *S. epidermidis* attachment or biofilm formation. Catheters that were precoated for 10 minutes, and catheters that were precoated
30 for 24 hours and then dried, were also resistant to colonization and biofilm formation by *S. epidermidis*.

Thus, as demonstrated by these experiments, addition of an isolated dispersin B protein as well as mutation of the *dspB* gene modulates the detachment of cells from

- 28 -

biofilm colonies of various bacteria, particularly bacteria with a biofilm comprising a polysaccharide containing N-acetylglucosamine. Fungi also form biofilms of clinical significance which may compromise polysaccharide containing
5 N-acetylglucosamine. It is believed that dispersin B will also be effective in degrading these fungal polysaccharides and modulating detachment of such fungal cells from their biofilms.

Accordingly, the present invention also relates to
10 methods for modulating detachment of bacterial or fungal cells from biofilms, particularly bacteria or fungal with a biofilm comprising a polysaccharide containing N-acetylglucosamine.

By "modulating detachment" as used herein it is meant
15 to be inclusive of increases as well as decreases in bacterial or fungal biofilm detachment or release of bacterial or fungal cells from the biofilm. Further, by "modulating detachment" it is also meant to be inclusive of changes in the ability of the bacteria or fungal to attach
20 as a biofilm. For example, as demonstrated herein, dispersin B modulates detachment of *S. epidermidis* not only by promoting detachment but also by inhibiting the ability of the bacteria to attach to surfaces and form a biofilm.

In one embodiment of the present invention, the
25 method comprises mutating *dspB* of bacterial cells to inhibit detachment of bacterial cells from biofilms such as in the JK1023 mutant of the present invention. In another embodiment, the method comprises decreasing expression and/or levels of soluble, β -N-acetylglucosaminidase or
30 inhibiting activity of soluble, β -N-acetylglucosaminidase in bacterial cells so that detachment of bacterial cells is decreased.

The present invention also provides methods for promoting detachment of bacterial or fungal cells from a
35 biofilm which comprises contacting bacterial or fungal

- 29 -

cells with soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof. For example, A.

5 *actinomycetemcomitans* dispersin B was found to detach biofilms of *Haemophilus aphrophilus*, *Actinobacillus pleuropneumoniae* and *S. epidermidis*. It is believed that biofilm detachment of *Actinobacillus ligniersii*, as well as other bacteria or fungi with a biofilm comprising a
10 polysaccharide containing N-acetylglucosamine including, but in no way limited to, *Staphylococcus aureus* and *Yersinia pestis* will also be promoted in the presence of soluble β -N-acetylglucosaminidase or an active fragment thereof of the present invention.

15 Accordingly, isolated dispersin B proteins and active fragments or variants thereof can be used to prevent or inhibit bacterial or fungal biofilm attachment and to treat infections by such bacteria or fungi.

In one embodiment, the isolated dispersin B protein
20 or active fragment or variant thereof is used directly as a parenteral to treat biofilm infections such as mastitis in ewes, intramammary infections in cows or osteomyelitis and infective endocarditis in humans. In this embodiment, the isolated soluble, β -N-acetylglucosaminidase protein or
25 active fragment or variant thereof is preferably administered as a pharmaceutical composition in a pharmaceutically acceptable carrier to an organism.

By "organism", as used herein it is meant to be inclusive of all animals including, but not limited to
30 mammals, and most preferably humans.

Any pharmaceutically acceptable vehicle or carrier, as well as adjuvant, can be used in the manufacture, dissolution and administration of pharmaceutical preparations comprising dispersin B protein or active
35 fragment or variant thereof. Such vehicles, carriers and

- 30 -

adjuvants are well known to those of skill in the art and described in text books such as *Remington's Pharmaceutical Sciences*, Mack Publishing Co., Easton, PA, 1985.

Appropriate concentrations of active composition to be
5 incorporated into pharmaceutical compositions can be routinely determined by those skilled in the art and is dependent upon the form of administration as well as the severity of the condition being treated.

Pharmaceutical formulations suitable for oral
10 administration may be provided in convenient unit forms including, but not limited to, capsules or tablets, each containing a predetermined amount of the dispersin B protein or active fragment or variant thereof; as a powder or granules; as a solution, a suspension or as an emulsion.
15 The dispersin B protein or active fragment or variant thereof can also be presented as a bolus, electuary, or paste. Tablets and capsules for oral administration may contain conventional excipients such as binding agents, fillers, lubricants, disintegrants, or wetting agents. The
20 tablets may be coated according to methods well known in the art. Timed release formulations, which are known in the art, may also be suitable. Oral liquid preparations may be in the form of, for example, aqueous or oily suspensions, solutions, emulsions, syrups or elixirs, or
25 may be presented as a dry product for constitution with water or other suitable vehicles before use. Such liquid preparations may contain conventional additives such as suspending agents, non-aqueous vehicles, including edible oils, or preservatives.

30 Dispersin B protein or active fragments or variants thereof of the present invention may also be formulated for parenteral administration, such as by injection, for example bolus injection or continuous infusion, and may be provided in unit dose form in ampules, pre-filled syringes,
35 small volume infusion or in multi-dose containers with an

- 31 -

added preservative. Pharmaceutically acceptable compositions comprising a dispersin B protein or active fragment or variant thereof for parenteral administration may be in the form of a suspension, solution or emulsion in
5 oily or aqueous vehicles, and may contain formulatory agents such as suspending, stabilizing, and/or dispersing agents. Alternatively, the active ingredient may be in powder form, obtained by aseptic isolation of sterile solid or by lyophilization from solution, for constitution
10 with a suitable vehicle such as sterile, pyrogen free water, before use.

For topical administration to the epidermis, dispersin B protein or an active fragment or variant thereof of the present invention may be formulated in an
15 ointment, cream, or lotion, or as a transdermal patch. Ointments and creams, may, for example, be formulated with an aqueous or oily base with the addition of suitable thickening and/or gelling agents. Lotions may be formulated with an aqueous or oily base and will in general
20 also contain one or more emulsifying agents, stabilizing agents, suspending agents, thickening agents, or coloring agents. Formulations suitable for topical administration in the mouth include lozenges comprising dispersin B protein or an active fragment or variant thereof in a
25 flavored base, usually sucrose and acacia or tragacanth; pastilles comprising the active ingredient in an inert base such as gelatin and glycerin or sucrose and acacia; and mouth washes comprising the active ingredient in a suitable liquid carrier. For topical administration to the eye, the
30 dispersin B protein or active fragment or variant thereof can be made up in solution or suspension in a suitable sterile aqueous or non-aqueous vehicle. Additives such as buffers (e.g. sodium metabisulphite or disodium edeate) and thickening agents such as hypromellose can also be
35 included.

- 32 -

For intra-nasal administration, dispersin B protein or an active fragment or variant thereof of the present invention can be provide in a liquid spray or dispersible powder or in the form of drops. Drops may be formulated
5 with an aqueous or non-aqueous base also comprising one or more dispersing agents, solubilizing agents, or suspending agents. Liquid sprays are conveniently delivered from pressurized packs.

For administration by inhalation, dispersin B protein
10 or active fragment or variant thereof of the present invention can be delivered by insufflator, nebulizer or a pressurized pack or other convenient means of delivering the aerosol spray. Pressurized packs may comprise a suitable propellant such as dichlorodifluoromethane,
15 trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount.

Alternatively, for administration by inhalation or
20 insufflation, the dispersin B protein or active fragment or variant thereof of the present invention can take the form of a dry powder composition, for example a powder mix of the active component and a suitable powder base such as lactose or starch. The powder composition may be presented
25 in unit dosage form in, for example, capsules, cartridges or blister packs of gelatins, from which the powder can be administered with the aid of an inhalator or insufflator.

When desired, any of the above-described formulations may be adapted to provide sustained release of the
30 dispersin B protein or active fragment or variant thereof.

The amount of dispersin B protein or active fragment or variant thereof of the present invention required for use in treatment will of course vary not only with the particular protein or active fragment or variant selected
35 but also with the route of administration, the nature of

- 33 -

the condition being treated, and the age and condition of the organism.

Increasing detachment of bacteria from a biofilm is also expected to decrease resistance of the bacteria to
5 antibiotic therapy. Accordingly, the present invention also provide methods for enhancing efficacy of antibiotic therapy against bacterial infections by administration of a pharmaceutical composition of the present invention in combination with or prior to administration of an
10 antibiotic.

In another embodiment of the present invention, wound dressings including but not limited to sponges or gauzes can be impregnated with the isolated dispersin B protein or active fragment or variant thereof to prevent or inhibit
15 bacterial or fungal attachment and reduce the risk of wound infections. Similarly, catheter shields as well as other materials used to cover a catheter insertion sites can be coated or impregnated with a dispersin B protein or active fragment or variant thereof to inhibit bacterial or fungal
20 biofilm attachment thereto. Adhesive drapes used to prevent wound infection during high risk surgeries can be impregnated with the isolated protein or active fragment or variant thereof as well. Additional medical devices which can be coated with a dispersin B protein or active fragment
25 or variant thereof include, but are not limited, central venous catheters, intravascular catheters, urinary catheters, Hickman catheters, peritoneal dialysis catheters, endotracheal catheters, mechanical heart valves, cardiac pacemakers, arteriovenous shunts, scleral buckles,
30 prosthetic joints, tympanostomy tubes, tracheostomy tubes, voice prosthetics, penile prosthetics, artificial urinary sphincters, synthetic pubovaginal slings, surgical sutures, bone anchors, bone screws, intraocular lenses, contact lenses, intrauterine devices, aortofemoral grafts and
35 vascular grafts. Exemplary solutions for impregnating

- 34 -

gauzes or sponges, catheter shields and adhesive drapes or coating catheter shields and other medical devices include, but are not limited to, phosphate buffered saline (pH approximately 7.5) and bicarbonate buffer (pH approximately 9.0).

In yet another embodiment, an isolated dispersin B protein or active fragment or variant thereof can be incorporated in a liquid disinfecting solution. Such solutions may further comprise antimicrobials or antifungals such as alcohol, providone-iodine solution and antibiotics as well as preservatives. These solutions can be used, for example, as disinfectants of the skin or surrounding area prior to insertion or implantation of a device such as a catheter, as catheter lock and/or flush solutions, and as antiseptic rinses for any medical device including, but not limited to catheter components such as needles, Leur-Lok connectors, needleless connectors and hubs as well as other implantable devices. These solutions can also be used to coat or disinfect surgical instruments including, but not limited to, clamps, forceps, scissors, skin hooks, tubing, needles, retractors, scalers, drills, chisels, rasps and saws.

The nucleic acid and amino acid sequences of the present invention, as well as the mutant JK1023 strain can also be used to identify agents which modulate detachment of bacterial or fungal cells from biofilms. For example, the ability of an agent to modulate activity and/or expression of soluble, β -N-acetylglucosaminidase of the present invention can be assessed.

Examples of such agents include, but are not limited to antisense oligonucleotides or ribozymes targeted to the *dspB* gene, peptidomimetics of dispersin B, and small organic chemicals such as quinacrine and NAG-thiazoline which modulate dispersin B activity and/or levels and/or expression.

- 35 -

Agents which inhibit the ability of soluble, β -N-acetylglucosaminidase to promote detachment of bacterial cells from biofilms are expected to be useful in preventing the dissemination of infectious bacteria, particularly
5 infectious bacteria of the oral cavity such as *A. actinomy-*
cetemcomitans and closely related bacterium such as
Haemophilus aphrophilus.

Agents which mimic dispersin B activity such as peptidomimetics and small organic molecules similar in
10 structure and activity to dispersin B can be used in
similar fashion to isolated dispersin B or an active
fragment or variant thereof to prevent, inhibit or treat
infection resulting from bacterial or fungal biofilm
attachment to surfaces. Such uses are described herein in
15 detail *supra*.

The present invention also provides primer pairs and kits comprising such primer pairs for use in identifying additional species of bacteria with dispersin B homologues. An exemplary degenerate primer pair useful in the kits of
20 the present invention comprises 5'-GAYCAYGARAAYTAYCG-3'
(SEQ ID NO:12) and 5'-TCNCCRTCRTARCTCCA-3' (SEQ ID NO:13),
where Y is C or T, and R is A or G. Kits of the present
invention preferably further comprise instructions for use
of the kit and/or positive and negative control samples.
25 Bacteria identified by these kits as having a dispersin B
homologue can be further examined to determine if the
homolog is an ortholog exhibiting the same or similar
enzymatic activity as dispersin B. The primers and kits of
the present invention are thus useful in identifying
30 additional bacteria, biofilm attachment of which can be
modulated using the nucleic acid sequences, amino acid
sequences, and agents described herein as well as
additional orthologous nucleic acid sequences and amino
acid of dispersin B.

35 The following nonlimiting examples are provided to

- 36 -

further illustrate the present invention.

Examples

Example 1: Bacterial strains and growth conditions

A. *actinomycetemcomitans* CU1000 (serotype f) is a
5 clinical strain isolated from a 13 year old patient with
localized juvenile periodontitis (Fine et al. Microbiol.
1999 145:1335-1347). Strain CU1000N is a spontaneous
nalidixic acid derivative of strain CU1000 that displays
the same surface attachment, biofilm colony formation and
10 biofilm dispersal phenotypes as the parental strain (Fine
et al. Arch. Oral Biol. 2001 46:1065-1078; Kachlany et al.
J. Bacteriol. 2000 182:6169-6176; Kachlany et al. Mol.
Microbiol. 2001 40:542-554; Thomson et al. J. Bacteriol.
1999 181:7298-7307). Mutagenesis of strain CU1000N with
15 transposon IS903 ϕ kan was carried in accordance with the
procedures set forth by Thomson et al. (J. Bacteriol.
1999 181:7298-7307). Other strains utilized include A.
actinomycetemcomitans DF2200 (serotype a), NJ8800 (serotype
b), NJ2700 (serotype c), and NJ9500 (serotype e) (Kaplan et
20 al. J. Clin. Microbiol. 2002 40:1181-1187); and A.
actinomycetemcomitans strain IDH781 (Saarela et al. Oral
Microbiol. Immunol. 1993 8:111-115); *Haemophilus*
aphrophilus NJ8700 (Kaplan et al. J. Clin. Microbiol. 2002
40:1181-1187); *Neisseria subflava* NJ9702 (Kaplan, J. B. and
25 Fine, D.H.. Appl. Environ. Microbiol. 2002 68:4943-4950);
Cardiobacterium hominis NJ6500; *Actinobacillus ligniersii*
strain 19393 (obtained from ATCC, Manassa, VA); and
Streptococcus mitis NJ9705 (Kaplan, J. B. and Fine, D.H..
Appl. Environ. Microbiol. 2002 68:4943-4950). *S.*
30 *epidermidis* strains were isolated from the surfaces of
infected intravenous catheters and were identified by using
the Api-Staph biochemical identification kit (Biomérieux,
Lyons France). *A. pleuropneumoniae* strains were obtained
from the Veterinary Diagnostics Laboratory (Iowa State

- 37 -

University, Ames, IL). Bacteria were grown in Trypticase soy broth (BD Biosystems) supplemented with 6 grams of yeast extract and 8 grams of glucose/liter. Inoculated culture vessels were incubated at 37°C in 10% CO₂, except
5 for *S. epidermidis* cultures, which were incubated at 37°C in air.

Example 2: Cloning and sequencing *dspB*

The transposon insertion site in *A. actinomycetemcomitans* mutant strain JK1023 was cloned and
10 sequenced by using an inverse PCR method in accordance with Kaplan et al. (Infect. Immun. 2001 69:5375-5384). The DNA sequence of the inverse PCR product was compared to the genome sequence of *A. actinomycetemcomitans* strain HK1651 from the Actinobacillus Genome Sequencing Project and the
15 transposon was found to have inserted into a long open reading frame (ORF) which was designated *dspB*. Primers that hybridize to sequences upstream and downstream from HK1651 *dspB* were used to amplify by PCR the *dspB* coding region from *A. actinomycetemcomitans* strain CU1000 using
20 methods in accordance with Kaplan et al. (Infect. Immun. 2001 69:5375-5384). The forward primer (5-GCGCGCCATatgAATTGTTGCGTAAAAGGCAATTCC-3 (SEQ ID NO:14)) introduced an *NdeI* restriction site (underlined) and an ATG initiation codon (lower case) at codon positions 19 to 20
25 of *dspB*, and the reverse primer (5-GCGGTACCCTCATCCCCATTCGTCTTATGAATC-3 (SEQ ID NO:15)) replaced the *dspB* stop codon with a *KpnI* restriction site (underlined). The PCR product (1,106 bp) was digested with *NdeI* and *KpnI* and ligated into the *NdeI*/*KpnI* sites of
30 plasmid pET29b (Novagen). The insert of the resulting plasmid (designated pRC1) was subjected to DNA sequence analysis in accordance with procedures described by Kaplan et al. (Infect. Immun. 2001 69:5375-5384).

Example 3: Expression and purification of recombinant

- 38 -

Dispersin B protein

Plasmid pRC1 carries a gene that encoded amino acids 21 to 381 of *dspB* fused to a 32 amino acid residue C-terminal tail containing an hexahistidine metal-binding site and a thrombin protease cleavage site which could be used to cleave the C-terminal tail from the hybrid protein. This gene was located downstream from an isopropyl- β -D-thiogalactopyranoside (IPTG)-inducible *tac* promoter.

Expression of DspB in E. coli

10 A one liter Erlenmeyer flask containing 500 ml of LB broth supplemented with 50 μ g/ml of kanamycin was inoculated with 5 ml of an overnight culture of *E. coli* strain BL21(DE3) (Dubendorff, J. W. and Studier, F. W. J. Mol. Biol. 1991 219:61-68) transformed with pRC1. The
15 flask was incubated at 37°C with agitation (200 rpm) until the optical density of the culture (measured at 280 nm) reached 0.6 (approximately 3 hours). IPTG was added to a final concentration of 0.2 mM and the flask was incubated for an additional 5 hours with agitation. The cells were
20 harvested by centrifugation for 15 minutes at 6,000 x g and the cell pellet was stored at -80°C.

Protein purification

The cell pellet was thawed on ice and resuspended in 20 ml of lysis buffer [20 mM Tris-HCl (pH 7.2), 0.1% sodium
25 dodecyl sulfate] containing 10 mg/ml lysozyme. The cell suspension was sonicated for 30 seconds at 50% capacity, 70% duty cycle in a Branson model 4550 sonicator equipped with a microprobe and then cooled on ice for 30 seconds. The sonication and cooling steps were repeated four
30 additional times. The cells were pelleted by centrifugation as above and the supernatant was transferred to a new tube. The cell pellet was resuspended in 20 ml of lysis buffer without lysozyme and five additional cycles of sonication and cooling were performed. The cells were pelleted by
35 centrifugation and the supernatant was removed and

- 39 -

transferred to a new tube. The two supernatants were combined and loaded onto a 3 ml bed volume Ni-affinity column (catalog no. 154-0990, Pharmacia) according to the instructions supplied by the manufacturer. The column was washed with 50 ml of wash buffer [50 mM MOPS (pH 8.5), 20 mM KCl] containing 5 mM imidazole, followed by 25 ml of wash buffer containing 50 mM imidazole and 25 ml of wash buffer containing 100 mM imidazole. Fractions (1.5 ml each) were collected during the final wash and assayed for the presence of the hybrid protein by SDS polyacrylamide gel electrophoresis (SDS-PAGE) and Coomassie blue staining in accordance with procedures described by Sambrook et al. (1989. Molecular cloning: a laboratory manual, 2nd ed. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y.).

Fractions containing the protein were pooled and dialyzed overnight against water using a 10,000 MW cut-off dialysis membrane. The purified protein was digested with 5 units of thrombin (Novagen) per mg of protein for 1 hour at room temperature and the thrombin was removed using a Thrombin Cleavage Capture Kit (Novagen) according to instructions supplied with the kit. Undigested protein was removed by loading the sample onto a Ni-affinity column as described above and washing the column with 10 ml of wash buffer containing 5 mM imidazole. Fractions of the wash (1.5 ml each) were collected and analyzed for the presence of the protein by SDS-PAGE. Fractions containing the protein were pooled, dialyzed against water, and stored at -20°C.

N-terminal sequence analysis of the purified protein was carried out using the Edman degradation procedure on a Beckman model 2300 protein sequencer. Mass spectra were determined by using a Hitachi model 4414 mass spectrometer.

Example 4: Enzyme assays

Synthetic substrates (purchased from Sigma Chemical Co.) were 4-nitrophenyl-N-acetyl- β -D-galactosaminide, 4-nitrophenyl-N-acetyl- α -D-galactosaminide, 4-nitrophenyl-N-

- 40 -

acetyl- β -D-glucosaminide, and 4-nitrophenyl-N-acetyl- α -D-glucosaminide. Enzyme reactions were carried out in a 10 ml volume containing 50 mM sodium phosphate buffer (pH 5.9), 100 mM NaCl, 5 mM substrate, and 3.7 μ g/ml purified protein in a 15 ml polypropylene tube placed in a 37°C water bath. The reaction was terminated at various times by transferring 1 ml of the reaction mixture to a new tube containing 5 μ l NaOH. The increase in absorption resulting from the release of p-nitrophenolate in each tube was measured in a Shimadzu UV-Mini spectrophotometer set to 405 nm.

Example 5: Identification of *dspB* orthologues in other strains of *A. actinomycetemcomitans* and in other species of bacteria

The microbial genome database www.ncbi.nlm.nih.gov was searched for homologues of *A. actinomycetemcomitans dspB*. *dspB* homologues were identified in the unfinished genomes of *A. pleuropneumoniae* serovars 1, 5 and 7. The *A. pleuropneumoniae dspB* homologues displayed approximately 60% identity at the amino acid level with the *A. actinomycetemcomitans* CU1000 DspB sequences. Additional searching was performed for DspB homologues in other members of the *Pasteurellaceae* family. The amino acid sequence of *A. actinomycetemcomitans* CU1000 DspB was aligned with the *A. pleuropneumoniae* DspB homologues and two regions of the sequence were identified that were highly conserved. Degenerate oligonucleotide primers were then synthesized that hybridized to DNA sequences encoding these conserved amino acids (5'-GAYCAYGARAAYTAYCG-3' (SEQ ID NO:12) and 5'-TCNCCRTCRTARCTCCA-3' (SEQ ID NO:13), where Y = C or T, R = A or G, and N = A or C or G or T) and these primers were used to amplify by PCR genomic DNAs purified from various species of *Pasteurellaceae*. A PCR product of the expected size was observed in genomic DNA from *A.*

- 41 -

actinomycetemcomitans strain IDH781 (Saarela et al. 1993. Oral Microbiol. Immunol. 8:111-115), *A. pleuropneumoniae* strain IA5 (obtained from the Veterinary Diagnostics Laboratory, Iowa State University, Ames, IA), *Haemophilus* 5 *aphrophilus* strain NJ8700 (Kaplan et al. 2002 J. Clin. Microbiol. 40:1181-1187), and *A. lignieresii* strain 19393 (obtained from the American Type Culture Collection, Manassas, VA). No PCR product was observed with DNA from *Haemophilus somnus*, *Actinobacillus equuli*, *Pasteurella* 10 *multocida*, and *Mannheimia haemolytica*.

The PCR products were cloned into multicopy plasmids and subjected to DNA sequence analysis. Figure 1 shows a comparison of the predicted *DspB* amino acid sequence of *A. actinomycetemcomitans* CU1000 *DspB* and the sequences of the 15 *DspB* homologues from the other strain of *A. actinomycetemcomitans* and other *Pasteurellaceae* bacteria.

Example 6: Overexpression of *dspB* in a wild-type strain of *A. actinomycetemcomitans*

In order to determine the effects of overexpressing 20 *dspB* in a wild-type strain of *A. actinomycetemcomitans*, a plasmid was constructed which contains *dspB* under the control of an isopropyl- β -D-thiogalactopyranoside (IPTG)-inducible promoter. This plasmid was introduced into wild-type strain CU1000, and the cells were grown in the 25 presence of 1 mM IPTG. CU1000 cells harboring the *dspB* expressing plasmid exhibited a smooth-colony morphology on agar and produced biofilm colonies in broth that displayed a hyper-dispersing phenotype, as indicated by the presence of increased numbers of satellite colonies on the surface 30 of the culture vessel. These findings confirm that *dspB* expression parallels the amount of biofilm dispersal.

Example 7: Detachment of biofilm cells from polystyrene rods in microtiter plates

An assay to measure the detachment of cells from

- 42 -

preformed biofilm colonies grown on polystyrene rods was carried out in 96-well microtiter plates. Biofilm colonies were grown on polystyrene rods suspended in broth in the 96-wells of a microtiter plate. Cells that detached from
5 the biofilm fell to the bottom of the well where they attached to the surface and formed new biofilm colonies. The amount of biofilm growth on the bottom of the well, which was proportional to the Number of cells that detached from the biofilm colonies on the rods, was measured by
10 staining with crystal violet. The detachment assay was carried out as follows.

Construction of the apparatus

The lid of a 96-well polystyrene flat-bottomed tissue culture plate (Falcon No. 353072) was modified as follows:
15 First, 96 1.5-mm diameter holes were drilled in the lid, with each hole in a position corresponding to the center of one of the 96 wells. Then, an 11-mm long polystyrene rod (1.5-mm diameter, Plastruct Corp., City of Industry, CA) was placed in each hole (with one end of the rod flush
20 against the top of the lid) and secured with trichloromethane plastic solvent. When this modified lid was placed on a 96-well microtiter plate bottom, the rods were suspended in the wells with the bottom of each rod approximately 2 mm above the bottom of
25 the well. The modified lid was sterilized by soaking in 70% ethanol for 30 minutes and air drying in a biological safety cabinet.

Inoculation and incubation of polystyrene rods

The microtiter plate bottom was filled with medium
30 (100 μ l per well) and each well was inoculated with a single 2-3 day old colony from an agar plate using a sterile toothpick. The modified lid was then placed on the inoculated plate to submerge the polystyrene rods in the inoculated medium, and the plate was incubated at 37°C for
35 24 hours to allow that bacteria to adhere to the rods. The

- 43 -

lid was then transferred to a fresh microtiter plate containing prewarmed medium and incubated for an additional 24 hours to allow biofilm cells to detach from the rods.

Measuring detached cells

5 The lid was removed and the plate was washed extensively under running tap water to remove loosely adherent cells. The wells were filled with 100 μ l of Gram-staining reagent (2 grams crystal violet, 0.8 grams ammonium oxalate, 20 ml ethanol per 100 ml) and the plate
10 was incubated at room temperature for 10 minutes. The plate was re-washed extensively under running tap water to remove unbound dye. The wells were then filled with 100 μ l of ethanol and the plate was incubated at room temperature for 10 minutes to solubilize the dye. The optical density
15 (at 590 nm) of the ethanol/dye solution in each well was measured using a Bio-Rad benchmark microplate reader.

Example 8: Growth of biofilms on polystyrene rods

Polystyrene rods (1.5 mm diam; Plastruct Corp., City of Industry, Calif.) were cut into 35 mm lengths,
20 sterilized in 70% ethanol for 30 minutes, and air dried in a biological safety cabinet. Rods were placed into 1.5 ml microcentrifuge tubes containing 0.5 ml of broth inoculated with *S. epidermidis* and incubated for 16 hours. Rods were then rinsed under running tap water and then placed in
25 fresh microcentrifuge tubes containing 0.5 ml of PBS or PBS plus dispersin B. Rods were rinsed with water and stained with crystal violet as previously described (Kaplan, J. B., and Fine, D. H. Appl. Environ. Microbiol. 2002 68:4943-4950). For sonication, rods were placed in 15 ml conical
30 centrifuge tubes containing 3 ml of PBS and then sonicated for 30 seconds at 40% duty cycle and 70% capacity in Branson model 200 sonicator equipped with a cup horn. For quantitation of detached cells, sonicates were serially diluted and plated on medium solidified with 1.5% agar.

35 **Example 9: Growth of biofilms in polystyrene microtiter**

- 44 -

plates

The wells of a 96-well polystyrene microtiter plate (model 3595, Corning) were filled with 100 μ l of broth inoculated with *S. epidermidis* and the plate was incubated for 16 hours. Microtiter plates were washed by aspirating the medium and washing the well three times with 200 μ l of PBS, or by submerging the entire plate in a tub of cold, running tap water. Biofilms were stained with crystal violet as previously described (Kaplan, J. B., and Fine, D. H. Appl. Environ. Microbiol. 2002 68:4943-4950).

Example 10: 96-well microtiter plate biofilm cell detachment assay

The wells of a 96-well microtiter plate (Falcon no. 353072) were filled with 100 μ l of medium containing 10^2 to 10^4 CFU of bacteria and incubated at 37°C in 10% CO₂ for 20 hours. Ten μ l of enzyme solution [1 mg ml⁻¹ in phosphate buffered saline (PBS)], or 10 μ l of PBS in the case of controls, was added to each well and the plates were incubated for an additional 6 hours. The wells were washed extensively under running tap water and the bacteria remaining attached to the surface were stained with crystal violet, rewashed, and destained with ethanol in accordance with procedures described by Kachlany et al. Mol. Microbiol. 2001 40:542-554). The optical density (O.D.) of the ethanol-dye solution was measured in a BioRad Benchmark microtiter plate reader set to 590 nm.

Example 11: Growth of biofilms on intravenous catheters

Polyurethane catheters (1.1 mm diam, model 381434, Becton-Dickinson) and Teflon catheters (1.2 mm diam, model 3055, Critikon) were employed. The tips of the catheters were plugged with sterile high vacuum grease to prevent media and dye from entering the lumen. Catheters were inoculated and treated as described above for polystyrene rods. Precoating of catheters with dispersin B was carried

- 45 -

out in PBS or in sodium phosphate buffer (pH 9) for 10 minutes to 24 hours. In some cases, coated catheters were air dried for 24 hours before use. Teflon catheters were stained with crystal violet as previously described

- 5 (Kaplan, J. B., and Fine, D. H. Appl. Environ. Microbiol. 2002 68:4943-4950). Polyurethane catheters were stained with 1% methylene blue in water for 2 minutes..

- 46 -

What is Claimed is:

1. An isolated nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof which promotes detachment of bacterial or
5 fungal cells from a biofilm.
2. The isolated nucleic acid sequence of claim 1 comprising a nucleic acid sequence with 50% sequence identity to at least 30 contiguous nucleotides of SEQ ID NO:1, 3, 5 7 or 9.
- 10 3. The isolated nucleic acid sequence of claim 1 comprising a nucleic acid sequence of SEQ ID NO:1, 3, 5 7 or 9.
4. A nucleic acid sequence encoding a fusion polypeptide comprising the isolated nucleic acid sequence
15 of claim 1, 2 or 3 and a second nucleic acid sequence encoding a second polypeptide.
5. A vector comprising the nucleic acid sequence of claim 1, 2, 3 or 4.
6. A host cell comprising the vector of claim 5.
- 20 7. An isolated amino acid sequence encoded by the nucleic acid sequence of claim 1, 2, 3 or 4.
8. An isolated soluble, β -N-acetylglucosaminidase protein or active fragment or variant thereof which promotes detachment of bacterial or fungal cells from a
25 biofilm.
9. The isolated soluble, β -N-acetylglucosaminidase protein or active fragment or variant thereof of claim 8

- 47 -

comprising SEQ ID NO:2, 4, 6, 8 or 10.

10. A fusion protein comprising the amino acid sequence of claim 8 or 9 and a second polypeptide.

5 11. A pharmaceutical composition comprising an effective amount of the isolated soluble, β -N-acetylglucosaminidase protein or active fragment or variant thereof of claim 8 or 9 and a pharmaceutically acceptable carrier.

10 12. A method for enhancing efficacy of an antibiotic against a bacterial infection comprising administering the pharmaceutical composition of claim 11 in combination with or prior to administration of the antibiotic.

15 13. A medical device coated with the isolated soluble, β -N-acetylglucosaminidase protein or active fragment or variant thereof of claim 8 or 9.

14. A wound healing device impregnated with the isolated soluble, β -N-acetylglucosaminidase protein or
20 active fragment or variant thereof of claim 8 or 9.

15. A liquid antiseptic solution comprising the isolated soluble, β -N-acetylglucosaminidase protein or active fragment or variant thereof of claim 8 or 9.

16. A method for inhibiting detachment of bacterial
25 or fungal cells from biofilm comprising mutating a *dspB* gene of bacterial cells to inhibit detachment of bacterial or fungal cells from biofilms.

17. A method for inhibiting detachment of bacterial or fungal cells from biofilm comprising decreasing

- 48 -

expression or levels of soluble, β -N-acetylglucosaminidase or inhibiting activity of soluble, β -N-acetylglucosaminidase in the bacterial cells so that detachment of bacterial or fungal cells from the biofilm is
5 decreased.

18. An isolated mutant of *Actinobacillus actinomycetemcomitans* which forms biofilm colonies which tightly adhere to surfaces but which are unable to release cells into the medium or spread over the surface.

10 19. The mutant of claim 18 wherein the *dspB* gene is mutated.

20. A method for identifying an agent which modulates detachment of bacterial or fungal cells from biofilms comprising assessing an agent's ability to
15 modulate activity or expression or levels of soluble, β -N-acetylglucosaminidase.

21. A method for promoting detachment of bacterial or fungal cells from a biofilm comprising contacting
20 bacterial cells with soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof so that detachment of bacterial or fungal cells from a biofilm is promoted.

25 22. A method for reducing risk of infection of an organism by bacteria or fungi on a medical device or surgical instrument comprising contacting the medical device or surgical instrument with soluble, β -N-acetylglucosaminidase or an active fragment or variant
30 thereof prior to contacting the organism with the medical device or surgical instrument.

- 49 -

23. The method of claim 22 wherein the medical device is coated with the soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof.

5 24. The method of claim 23 wherein the coating of soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof is dried on the medical device.

25. The method of claim 22 wherein the medical device is a catheter and the soluble, β -N-
10 acetylglucosaminidase or an active fragment or variant thereof is in a catheter lock solution in the catheter.

26. A method for inhibiting, preventing or treating bacterial or fungal infections comprising administering to an organism soluble, β -N-acetylglucosaminidase or an active
15 fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof so that detachment of bacterial or fungal cells from a biofilm is promoted.

27. The method of claim 26 wherein the bacterial or
20 fungal infection is from a bacterium or fungus that produces a N-acetylglucosaminidase containing biofilm polysaccharide that can be degraded by soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof.

25 28. The method of claim 26 wherein the soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof is administered as a coating on a medical device
30 implanted in the organism.

- 50 -

29. The method of claim 26 wherein the soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant
5 thereof is administered as a pharmaceutical composition.

30. The method of claim 26 wherein the soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant
10 thereof is incorporated into a liquid disinfecting solution and applied topically to the subject prior to insertion of an implantable medical device.

31. The method of claim 26 wherein a wound dressing applied to the subject is impregnated with the soluble, β -
15 N-acetylglucosaminidase or an active fragment or variant thereof or a nucleic acid sequence encoding soluble, β -N-acetylglucosaminidase or an active fragment or variant thereof.

32. A primer pair which identifies bacteria with
20 *DspB* homologs.

33. The primer pair of claim 32 comprising SEQ ID NO:12 and SEQ ID NO:13.

25 34. A kit for identifying bacteria with *DspB* homologs comprising the primer pair of claim 32 or 33 and instructions for use of the primer pair to identify bacteria with *DspB* homologs.
